# **Gunpowder Injury Decision Tree**

# Introduction and Overview of Decision Problem

In Columbia, the issue of gunpowder-related injuries, particularly during festive seasons, remains a significant public health concern. Fireworks, while culturally ingrained and a source of celebration, pose substantial risks, especially to children. This has led policymakers to consider various strategies to mitigate these risks and enhance public safety.

The decision problem we will consider revolves around analyzing approaches to reducing injuries and fatalities caused by fireworks. Two primary strategies under consideration are (1) a complete ban on fireworks and (2) heavy regulation, such as restricted sales licenses and stringent enforcement.

A complete ban aims to eliminate the root cause of injuries by prohibiting the sale, storage, and use of fireworks. This approach seeks to protect public health directly but may face resistance due to its impact on cultural traditions and the livelihoods of vendors.

On the other hand, heavy regulation involves implementing strict controls over the sale and use of fireworks. This strategy includes measures such as issuing sales licenses only to authorized vendors, enforcing age restrictions, and conducting public education campaigns about the dangers of fireworks. This approach aims to reduce injuries while allowing for controlled, safe use of fireworks.

Our case studies will explore these strategies through two decision modeling approaches. This case study will utilize a decision tree model to evaluate the immediate outcomes and costs associated with each strategy.

Later, we will employ a Markov cohort model to examine the long-term health and economic impacts, considering factors such as injury rates, healthcare costs, and compliance levels.

By analyzing these models, we aim to provide a comprehensive assessment of the most costeffective and sustainable approach to reducing gunpowder-related injuries in Columbia today.

# **Model Inputs and Parameters**

## **Injury Rates**

Your colleagues have compiled the following data on gunpowder injuries by year in Columbia. We will construct a decision tree model based on injuries in the most recent year reported (2022).

Year	Cases PopulationRate.per.100.000		
2017	1,778 47,419,000	3.75	
2018	1,477 $48,259,442$	3.06	
2019	1,378 49,269,676	2.80	
2020	1,504 50,407,437	2.98	
2021	1,694 51,177,378	3.31	
2022	1,510 51,826,932	2.92	

### **Injury Types and Consequences**

We will assume that reported injuries fall into three major categories:

- Minor Or Moderate Injury: First-degree burns, which may cause pain, redness, and minor swelling. This category also includes second-degree burns that cover a more significant portion of the body and involve blisters, pain, and potential infection risk
- Major Injury: third-degree burns or severe trauma that affects deeper tissues and can lead to significant complications.
- Fatal Injury
- There are very likely many minor and moderate injuries that go unreported in official statistics. For this case study, we will assume that severe injuries are 30% of reported injuries.

Description	Base Case Value	Parameter Name
Probability of Injury Probability Injury is Severe Probability Injury is Fatal	0.0000292 0.30 0.0046	p_injury p_severe p_fatality

We will also assume that a small percentage (15%) of individuals with mild/moderate injuries experience long-term consequences (i.e., 85% recover), while the majority (60%) of those with severe injuries do not fully recover and experience long-term complications.

Description	Base Case Value	Parameter Name
Probability of Recovery: Mild/Moderate	0.85	p_recover_mildmod
Injury Probability of Recovery: Major Injury	0.4	p_recover_severe

## **Strategies and Impact**

When the mayor of Bogota banned the sale of fireworks in 1995, fireworks-related burns fell by 62%, from 204 in the 1994-1995 Christmas season to 77 during the 1995-1996 season. We will assume a similar 60% relative risk reduction under the "Ban" scenario.

By comparison, we will assume that stricter regulation will reduce firework injuries by just 15%. We will examine the sensitivity of our findings to these assumptons later in the case study.

#### **Exercises**

## 1.1. Build a "Do Nothing" Strategy

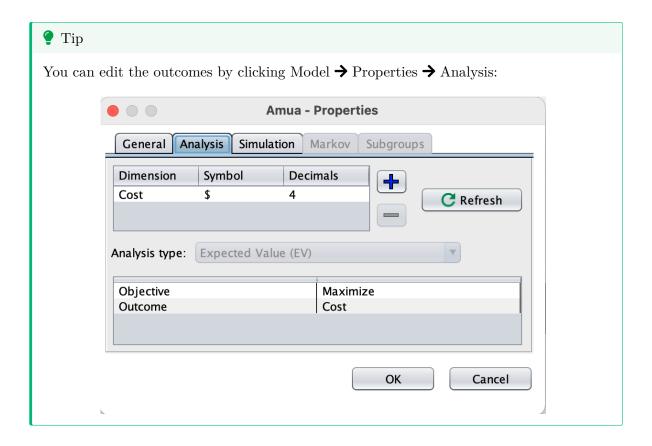

Construct a decision tree in Amua for a "Do Nothing" strategy. Your tree should work through the following chance nodes:

- 1. Injury vs. No Injury
- 2. Fatal injury vs. non-fatal injury
- 3. Mild/Moderate vs. Severe injury
- 4. Recovery vs. Recovery with Injury Sequale

Please use the parameter names and values supplied above in the construction of your tree.

#### 1.2. Add Outcomes

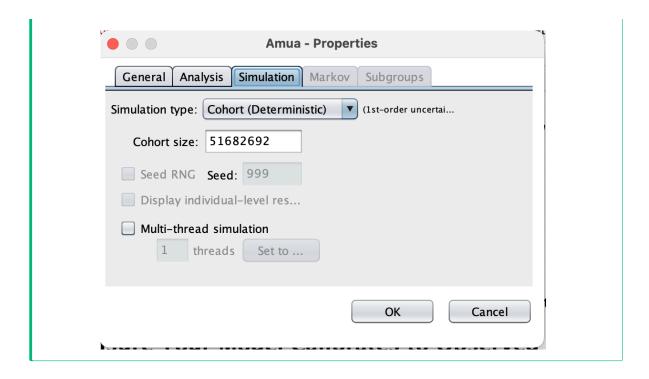

Amua defaults to cost outcomes. Please remove the cost outcome and define a new primary outcome based on injury. In other words, the outcome "payoff" should be 1.0 if an injury occurs, and 0 otherwise.

# 1.3. Ensure Your Model Calibrates to Observed Injury Totals

Run your initial decision tree using a cohort size of 51,682,692 (2022 population of Columbia). Verify that the total number of firework injuries closely matches the reported total of 1,510.

## 2.1. Include Additional Policy Scenarios

Create a duplicate version of your "Do Nothing" tree to construct separate branches for the "Ban" and "Regulate" scenarios. Under each, the probability of injury should be modified by a relative risk reduction parameter with values set based on the text above and the table below.

Description	Base Case Value	Parameter Name
Relative risk reduction: probability of injury	0.6	rr_ban
under "Ban" policy scenario Relative risk reduction: probability of injury	0.85	rr_ban
under "Regulate" policy scenario		

You can copy and paste the "Do Nothing" branch by right-clicking on the first chance node and selecting "Copy." You can then paste a copy of the entire tree structure on the red decision node .

# 2.2. Add Additional Outcomes

Add additional outcomes based on each injury type (mild/moderate, severe, fatal). Use your decision tree to project injuries overall and by type under each strategy. Use your results to fill out the table below. Each cell should have calculated counts of the number of each type of injury under each strategy.

Strategy	Any Injury	Mild/Moderate	Severe	Fatal
Do Nothing Ban Fireworks Regulate Fireworks
